

Synthetic lithium monitoring protocol

Synthetic test document for RAG demonstration only. Not a clinical guideline and not medical advice.

Lithium baseline checklist

- Confirm indication, formulation, target range, recent renal function, thyroid function, calcium, weight, blood pressure, and current interacting medicines.
- Record baseline mood symptoms and risk context. For the synthetic Perth clinic workflow, document the monitoring owner and the review interval before prescribing.
- Avoid relying on a single serum level without clinical context, hydration status, timing since last dose, and recent medicine changes.

Monitoring schedule

- In this synthetic protocol, check lithium level 5 to 7 days after initiation or dose change, then repeat until stable.
- After stability, the sample schedule uses lithium level every 3 months, renal and thyroid tests every 6 months, and calcium annually.
- Escalate review when there is vomiting, diarrhoea, dehydration, acute kidney injury, new NSAID/ACE inhibitor/diuretic exposure, tremor, confusion, or ataxia.
